To the editor,

Asthma is the most common and important chronic non-infectious disease in childhood and its prevalence has increased in the last years\textsuperscript{1}. However, information on childhood asthma prevalence research regarding Portuguese young children is scarce and has not been compiled. Therefore, as part of the INAIRCHILD project\textsuperscript{2}, this letter aimed to review the major scientific findings, of the most recently published papers on childhood asthma prevalence in Portuguese preschool aged children.

Articles published from 2005 to date were identified in the following on-line databases: Science Direct, Scopus, PubMed, and Google Scholar. Only studies in press or fully published (in English and/or Portuguese) were analysed. Although 8 studies were found published in the last 10 years on the assessment of childhood asthma prevalence in Portuguese young children, only two of them were focusing on preschool aged children.

Thus, this letter reviews those only two published papers, one recently published\textsuperscript{3} and the other one published 5 years ago\textsuperscript{4}, namely concerning study design, methodologies used, prevalence rates and risk factors.

Table 1 summarizes the main characteristics of these two reviewed studies. Both of these studies were cross-sectional and they were conducted in big urban areas in the coast line, although Branco et al.\textsuperscript{3} was also conducted in rural areas of the inner country (Bragança district) allowing comparisons between different geographic, social and demographic contexts. Different study population sizes were considered, but the aim was the same. Different methodologies were used to recruit study population and to obtain health information, although in both ISAAC-derived questionnaires were used, which allowed asthma prevalence estimation based on symptoms and asthma previously diagnosed. However, the comparison of asthma prevalence results between the two studies is difficult
due to different criteria used for asthma diagnosis, namely: i) combination of answers
given by the patient about respiratory symptoms and physician’s best knowledge of the
patient’s asthma status⁴; and ii) wheezing and dyspnea simultaneously mentioned in the
absence of upper respiratory infections³. In fact, de Sousa et al.⁴ assumed to have found
a lower prevalence for preschool age than expected due to diagnostic problems (the
diagnostic procedures were based on a combination of the answers given by the patient
on respiratory symptoms and the physician’s best knowledge of the patient’s asthma
status). Thus, the difference between the asthma prevalence values found in the two
studies should be interpreted with caution, because it could possibly be due to different
methodologies used and different criteria considered for asthma diagnosis. Moreover,
other factors like children’s age and environmental contexts were also different, which
could contribute to differences in the prevalence results.

In these two studies medical exams for asthma diagnosis confirmation were not
performed, like exhaled nitric oxide or spirometry. Although not very common in
preschool children, spirometry seems to be feasible in that age⁵. They have been used
worldwide to confirm asthmatic symptoms reported in questionnaires⁶, which is very
important to increase the robustness of the conclusions.

Risk factors for childhood asthma prevalence, namely demographic, environmental,
psychosocial and clinical risk factors, were only studied in Branco et al.³ which concluded
that living in a non-rural location, being male and having an asthmatic parent were risk
factors for childhood asthma development in Portuguese preschool children. However,
other important risk factors for childhood asthma development already reported in the
literature for primary school aged children were not considered, namely exposure to air
pollution⁷.
These findings led to conclude that asthma studies on Portuguese preschool children are rare and limited due to methodological constraints, namely to obtain precise health information and to perform medical exams to confirm symptoms. More studies are needed, particularly in preschool age children living both in urban and rural areas. Those studies should include medical exams to confirm asthma symptoms. The study of lifestyle risk factors must be enlarged to others already studied in primary school children.
