Background: The elevation of serum homocysteine is an independent and significant risk factor for vascular diseases. The prevalence of hyperhomocysteinemia in the general population is between 5-10%, and these values increase to 30 to 40% in the elderly. Some studies have documented a decrease of homocysteine levels with moderate consumption of beer. However, this inverse association lacks experimental evidence. Objective: To evaluate, in older adults, the effectiveness of non-alcoholic beer and non-alcoholic beer with a high content of folic acid in reducing hyperhomocysteinemia.

Participants and Methods: A quasi-experimental study, involving 40 older adults with advanced age with high serum homocysteine levels (>11µmol/L in women and >12µmol/L in men) was conducted. The older adults were divided into three groups. During a period of three weeks, the control group (n=23) consumed 500mL of water per day, the second group (n=8) 500ml non-alcoholic beer per day and the third group had 500 ml non-alcoholic beer with a high content of folic acid (40µg/100mL) daily. Levels of homocysteine, folic acid and cobalamin were evaluated at baseline and after this intervention.

Results: No statistical significance differences between groups were found at baseline and at the end of the intervention for the levels of folic acid and cobalamin. A decrease of homocysteine levels was observed in the group supplemented with non-alcoholic beer with high folic acid content (mean=3.55µmol/L, interquartile range=2.1µmol/L) compared to the control group (0.9µmol/L, interquartile range=1.5µmol/L), p<0.05. A non statistically significant reduction was also observed between the control group and the alcohol-free beer group (2.45 mmol/L, interquartile range = 6.3 mmol/L).

Conclusion: Non-alcoholic beer with a high content of folic acid intake during three weeks significantly decreased homocysteine levels in older adults with advanced age.

Key-words: folic acid, cobalamin, homocysteine, non-alcoholic beer, older adults with advanced age.
